

**Supplemental Figure 1: Serum albumin extravasation into the cortex three days after SE was used to evaluate integrity of the blood-brain barrier.** Albumin (green bands) and GAPDH (red bands) protein levels in cortical homogenates of mice treated with vehicle (V, n=20) or CCR2 antagonist (D, n=19) after kainic acid-induced status epilepticus shown over 5 blots. A total of 8 samples had running irregularities were rerun for evaluation. The 8 samples were rerun correctly and are shown in the blots.
